

All four panels are drawn for the same NV and the same 80-90  $\mu\text{m}$  layer; rays run from the collection core outward, which by reciprocity is the path a photon takes to reach it. Hatched bars (SM, MM) are bare fibers taken from the characterisation model, a different tracer, so only the two MCF tips are a like-for-like ratio. Collection is held to the escape-cone ceiling at every wavelength.
